Results and discussion
Blackbox optimization problems

We consider the optimization problem:

$$
\min_{x \in \Omega} f(x)
$$

with \( \Omega = \{ x \in X : c_j(x) \leq 0, j \in \{1, 2, \ldots, m\} \} \subset \mathbb{R}^n \).

The evaluations of \( f \) and of the \( c_j \) functions are usually the result of a computer code (a blackbox).
Blackboxes as illustrated by J. Simonis [ISMP 2009]
Mesh Adaptive Direct Search (MADS)

- Audet and Dennis [SIOPT, 2006]
- Iterative algorithm that evaluates the blackbox at some trial points on a spatial discretization called the mesh.
- One iteration = search and poll.
- The search allows trial points generated anywhere on the mesh.
- The poll consists in generating a list of trial points constructed from poll directions. These directions grow dense.
- At the end of the iteration, the mesh size is reduced if no new iterate is found.
- Algorithm is backed by a convergence analysis based on the Clarke Calculus for nonsmooth functions.
- MADS is available via the NOMAD free software package at www.gerad.ca/nomad.

Static versus dynamic surrogates

- **Static surrogate**: A cheaper model defined a priori by the user. It is used as a blackbox too. Typically a simplified physics model. Variable precision is not yet considered.

- **Dynamic surrogate**: Model managed by the algorithm, based on past evaluations. It can be periodically updated.

In the remaining of this presentation, we focus on dynamic surrogates based on the dynaTree library.
General framework of MADS + surrogates

Only the additions to the MADS algorithm are reported.

[0] Initializations

[1] Iteration $k$

[1.1] Model Search
- select data points from cache
- construct one model for each output (obj + cstrs)
- select points for model improvement
- optimize model to determine oracle points
  \((\rightarrow \text{the subproblem, or surrogate problem})\)
- project candidates to the mesh
- evaluate candidates opportunistically

[1.2] Poll (if the Search failed)
- Model Ordering: use models to sort trial points

[2] Updates
The dynaTree library

- Based on Bayesian inference.
- R package available on CRAN.
**dynaTree outputs**

- The predictive mean \( \hat{f}(x) \).
- The predictive standard deviation \( \hat{\sigma}_f(x) \).

- The predictive cumulative distribution \( \mathbb{P}[f(x) \leq f_0] \).
- Likewise for the constraints: \( \hat{c}_j(x), \hat{\sigma}_j(x), \mathbb{P}[c_j(x) \leq c_0] \).
Blackbox optimization and the MADS algorithm

Surrogates

**Surrogate problem formulations**

Results and discussion
Surrogate problem formulations

▶ At each iteration, find the most promising candidates by solving the surrogate problem.

▶ The most basic formulation is:

\[
\begin{align*}
\min_{x \in \mathcal{X}} & \quad \hat{f}(x) \\
\text{s.t.} & \quad \hat{c}_j(x) \leq 0 \quad \forall j \in J.
\end{align*}
\]

▶ We tested other formulations in the following submitted manuscript: B. Talgorn, S. Le Digabel, and M. Kokkolaras: *Problem Formulations for Simulation-based Design Optimization using Statistical Surrogates and Direct Search* [Optimization Online].
Diversification term

The standard deviation is added to the blackbox outputs:

\[ (F\sigma) \begin{cases} \min_{x \in \mathcal{X}} & \hat{f}(x) - \lambda.\hat{\sigma}_f(x) \\ \text{s.t.} & \hat{c}_j(x) - \lambda.\hat{\sigma}_j(x) \leq 0 \quad \forall j \in J. \end{cases} \]

\[ \lambda > 0 \Rightarrow \text{diversification}: \text{ focus more on exploration than on a particular region. The feasible domain is extended and poor values of } \hat{f} \text{ may be considered if } \hat{\sigma}_f \text{ is large.} \]
Probability of feasibility of a point

One continuous dynasty tree model is built for each constraint.

\[ P[x] = P[x \text{ is feasible}] = \prod_{j \in J} P[c_j(x) \leq 0]. \]

⇒ one scalar statistical measure to handle the constraints.
**Chance constraint**

\[
(F\sigma P) \quad \begin{cases} 
\min_{x \in X} & \hat{f}(x) - \lambda.\hat{\sigma}_f(x) \\
\text{s.t.} & \mathbb{P}[x \text{ is feasible}] \geq p_c
\end{cases}
\]

Diversification is possible (with parameter $\lambda$), but only candidates which are likely to be feasible are evaluated.

Generally, $p_c = \frac{1}{2}$, but it can be tailored according to the number of constraints.
**Improvement**

**Improvement:** \( I(x) = \max\{f_{\min} - f(x), 0\} \):

- M. Schonlau, D.R. Jones, and W.J. Welch [JOGO, 1998].
- \( f_{\min} \): current best known solution value.
- \( I(x) > 0 \) if \( x \) is better than the incumbent solution.
- \( I(x) = 0 \) otherwise.

Two statistical measurements:

- Probability of improvement: \( PI(x) = \mathbb{P}[I(x) > 0] \).
- Expected improvement: \( EI(x) = \mathbb{E}[I(x)] \).

What to do with constraints?
Probability of feasible improvement

Probabilities on:

- The objective: $PI(x)$
- The feasibility: $\mathbb{P}[x]$

$\Rightarrow$ Probability of Feasible Improvement:

$$PFI(x) = \mathbb{P}[x \text{ is feasible}] \times PI(x)$$

$$\min_{x \in \mathcal{X}} -PFI(x)$$
Expected improvement subject to constraints

Maximization of the expected improvement under constraints:

\[
\begin{aligned}
&\left\{ \min_{x \in \mathcal{X}} -EI(x) - \lambda \hat{\sigma}_f(x) \\
&\text{s.t. } \hat{c}_j(x) - \lambda \hat{\sigma}_j(x) \leq 0 \quad \forall j \in J
\end{aligned}
\]
Expected feasible improvement (EFI)

Statistical measurement of

- The objective: $EI(x)$
- The feasibility: $\mathbb{P}[x]$

$\Rightarrow$ Expected Feasible Improvement:

$$EFI(x) = \mathbb{P}[x \text{ is feasible}] \times \mathbb{E}[I(x)]$$

The EFI represents what a candidate will statistically yield, in regard to the optimization problem.
Expected feasible improvement (EFI)

Maximization of the expected feasible improvement:

\[
(FI) \quad \left\{ \min_{x \in \mathcal{X}} -EFI(x) \right\}
\]

\(EFI\) with a diversification term:

\[
(FI\sigma) \quad \left\{ \min_{x \in \mathcal{X}} -EFI(x) - \lambda \hat{\sigma}_f(x) \right\}
\]
Expected feasible improvement with $\mu$

$$\mu(x) = 4\mathbb{P}[x](1 - \mathbb{P}[x])$$

$\mu(x)$ represents the uncertainty on the feasibility (variance of a Bernoulli law of probability $\mathbb{P}[x]$).

$$(EFI\mu) \begin{cases} \min_{x \in \mathcal{X}} -EFI(x) - \lambda.\hat{\sigma}_f(x).\mu(x) \end{cases}$$

$\Rightarrow$ diversification favours a candidate with uncertainties on the objective AND the feasibility.
Crossed diversification terms

Search for candidates with:

promising objective (high $EI$) AND uncertain feasibility (high $\mu$)

OR

uncertain objective (high $\hat{\sigma}_f$) AND promising feasibility (high $\mathbb{P}[x]$)

$\Rightarrow$ Diversification term : $EI(x)\mu(x) + \hat{\sigma}_f(x)\mathbb{P}[x]$

Realistic MDO application

- NASA Aircraft Range problem with $n = m = 10$.
- Supersonic business jet with 3 disciplines: aerodynamics, structure, and propulsion.
- The problem can be summarized as

$$\begin{align*}
\text{max} & \quad \text{aircraft range} \\
\text{subject to} & \quad \text{normalized stress} \leq 1.09 \quad (5 \text{ constraints}) \\
& \quad \text{pressure gradient} \leq 1.04 \ \text{Pa.m}^{-1} \\
& \quad 0.5 \leq \text{eng. scale factor} \leq 1.5 \\
& \quad \text{normalized engine temperature} \leq 1.02 \\
& \quad \text{throttle setting} \leq \text{max throttle}
\end{align*}$$

Current conclusions

- Set of 20 analytic problems: $(F\sigma)$ with $\lambda = 1$ performs better.

- For two realistic MDO applications, $(EI\sigma)$ with $\lambda = 1/100$ and 1, and $(EFI\sigma)$ with $\lambda = 1/10$, gave the best results.

- NOMAD with dynaTree should be available in a future NOMAD release.
