## Linear programming

$$(LP) \quad z^{\text{LP}} = \min_x c^{\top} x \quad (1)$$

$$\text{s.t.} \quad Ax = b \quad (2)$$

$$x \geq 0 \quad (3)$$

where  $x \in \mathbb{R}^n$ ,  $c \in \mathbb{R}^n$ ,  $b \in \mathbb{R}^m$ , and  $A \in \mathbb{R}^{m \times n}$

- 1 Introduction
- 2 Improved Primal Simplex IPS
  - The reduced problem
  - The complementarity problem
  - IPS Non-aggregated Algorithm: IPS-N
  - Compatibility Matrix
- 3 Column generation for degenerate linear programs
  - Aggregated columns
  - IPS aggregated Algorithm: IPS-A
  - Numerical results
- 4 IPS specialization to set partitioning problems

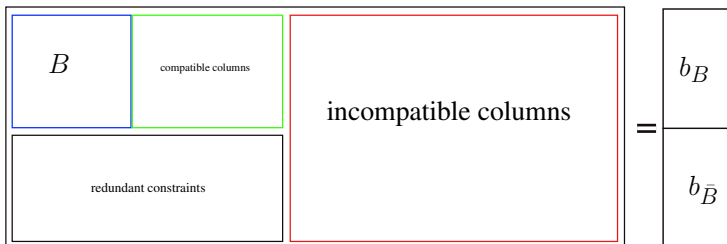

Figure 1: IPS decomposition of a linear program

Figure 2: Reduced Problem  $RP_B$

## Motivation

We know that a solution  $x$  is an optimal solution of  $LP$  if and only if there exists a dual solution  $\pi$  to  $LP$  such that

$$\bar{c}_j := c_j - \pi^\top A_j = 0, \quad \forall j \in \{1 \dots d\} \quad (4)$$

$$\bar{c}_j := c_j - \pi^\top A_j \geq 0, \quad \forall j \in \{d + 1 \dots n\} \quad (5)$$

## Motivation

We know that a solution  $x$  is an optimal solution of  $LP$  if and only if there exists a dual solution  $\pi$  to  $LP$  such that

$$\bar{c}_j := c_j - \pi^\top A_j = 0, \quad \forall j \in \{1 \dots d\} \quad (4)$$

$$\bar{c}_j := c_j - \pi^\top A_j \geq 0, \quad \forall j \in \{d + 1 \dots n\} \quad (5)$$

## Complementarity problem

$$\max_{s, \pi} \quad s \quad (6)$$

$$\text{s.t.} \quad c_j - \pi^\top A_j = 0, \quad \forall j \in \{1 \dots d\} \quad (7)$$

$$c_j - \pi^\top A_j \geq s, \quad \forall j \in I = \{d + 1 \dots n\} \quad (8)$$

Let  $A_B = \begin{pmatrix} A_B^1 \\ A_B^2 \end{pmatrix}$  be a submatrix of  $A$  composed of columns indexed in  $B$  where  $A_B^1$  is without loss of generality composed of the first  $|S|$  linearly independent rows.  $A_B^2$  is of course composed of redundant rows.

### Duality of complementarity problem

$$(CP_B) \quad z_B^{\text{CP}} = \min_{\lambda} \sum_{j \in I} \lambda_j \bar{c}_j \quad (9)$$

$$\text{s.t.} \quad MA_{\mathcal{I}} \lambda = 0 \quad (10)$$

$$\sum_{j \in I} \lambda_j = 1 \quad (11)$$

$$\lambda \geq 0. \quad (12)$$

with  $M = (A_B^2 (A_B^1)^{-1}, -I_{m-p})$  is a compatibility Matrix.  $A_{\mathcal{I}}$  is a matrix of incompatible columns.

Let  $A_B = \begin{pmatrix} A_B^1 \\ A_B^2 \end{pmatrix}$  be a submatrix of  $A$  composed of columns indexed in  $B$  where  $A_B^1$  is without loss of generality composed of the first  $|S|$  linearly independent rows.  $A_B^2$  is of course composed of redundant rows.

### Duality of complementarity problem

$$(CP_B) \quad z_B^{\text{CP}} = \min_{\lambda} \sum_{j \in I} \lambda_j \bar{c}_j \quad (9)$$

$$\text{s.t.} \quad MA_{\mathcal{I}} \lambda = 0 \quad (10)$$

$$\sum_{j \in I} \lambda_j = 1 \quad (11)$$

$$\lambda \geq 0. \quad (12)$$

with  $M = (A_B^2 (A_B^1)^{-1}, -I_{m-p})$  is a compatibility Matrix.  $A_{\mathcal{I}}$  is a matrix of incompatible columns.

A matrix  $M$  is said to be a compatibility matrix if and only if  $M D = 0$  for every compatible column  $D$ .

Let  $x_B^*$  an optimal solution of  $RP_B$  and  $\lambda^*$  an optimal solution of  $CP_B$

### Proposition

- If  $z_B^{CP} \geq 0$ , then  $(x_B^*, 0)$  is an optimal solution to LP.
- If  $z_B^{CP} < 0$ , then  $(x_B^*, 0)$  is not an optimal solution to LP.

Let  $x_B^*$  an optimal solution of  $RP_B$  and  $\lambda^*$  an optimal solution of  $CP_B$

### Proposition

- If  $z_B^{CP} \geq 0$ , then  $(x_B^*, 0)$  is an optimal solution to LP.
- If  $z_B^{CP} < 0$ , then  $(x_B^*, 0)$  is not an optimal solution to LP.
- Add  $\{A_j / \lambda_j^* > 0\}$  to  $RP_B \Rightarrow$  the optimal value decreases.

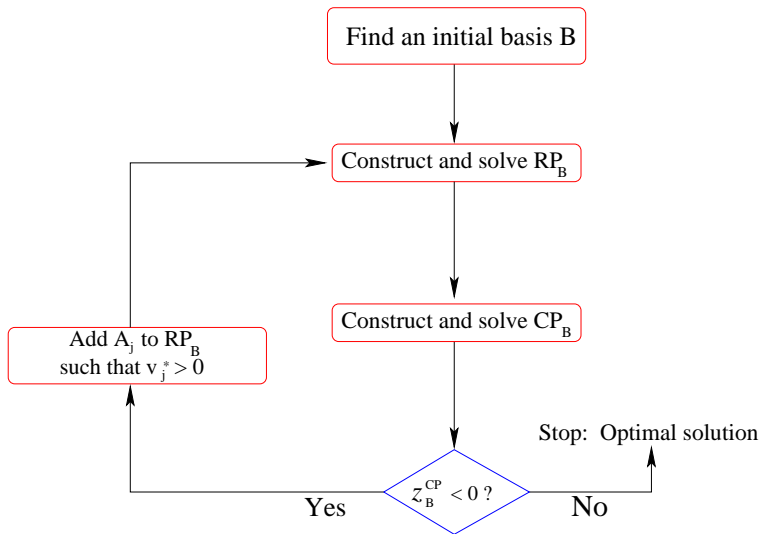

Figure 3: The Non-aggregated improved primal simplex algorithm (IPS-Non-aggregated)

## Compatibility Matrix: open questions

There is an infinity of compatibility matrices: if  $P$  is an invertible matrix and  $M$  a compatibility matrix, then  $PM$  is also a compatibility matrix.

Some of the roles of the compatibility matrix is a distinction between the compatible columns and incompatible columns.

Question: How to find the **best** compatibility matrix?

- Good classification of incompatibility columns
- Good numerical results (sparsity of matrices)

- 1 Introduction
- 2 Improved Primal Simplex IPS
  - The reduced problem
  - The complementarity problem
  - IPS Non-aggregated Algorithm: IPS-N
  - Compatibility Matrix
- 3 Column generation for degenerate linear programs**
  - Aggregated columns
  - IPS aggregated Algorithm: IPS-A
  - Numerical results
- 4 IPS specialization to set partitioning problems

- The same reduced problem  $RP_B$

- The same complementarity problem:

$$(CP_B) \quad z_B^{\text{CP}} = \min_{\lambda} \sum_{i \in I} \lambda_i \bar{c}_i \quad (13)$$

$$\text{s.t.} \quad MA_{\mathcal{I}} \lambda = 0 \quad (14)$$

$$\sum_{j \in I} \lambda_j = 1 \quad (15)$$

$$\lambda \geq 0. \quad (16)$$

- The same reduced problem  $RP_B$

- The same complementarity problem:

$$(CP_B) \quad z_B^{\text{CP}} = \min_{\lambda} \sum_{i \in I} \lambda_i \bar{c}_i \quad (13)$$

$$\text{s.t.} \quad MA_{\mathcal{I}} \lambda = 0 \quad (14)$$

$$\sum_{j \in I} \lambda_j = 1 \quad (15)$$

$$\lambda \geq 0. \quad (16)$$

- Add the aggregated column  $\omega = \sum_{j \in I} \lambda_j A_j$  in  $RP_B$

Let  $I = \{d + 1, \dots, n\}$  the index set of incompatible columns,  $\omega = \sum_{i \in I} v_i A_i$  with

$$\sum_{i \in I} v_i = 1, \quad \bar{c}_\omega = \sum_{i \in I} v_i \bar{c}_i.$$

$$\Omega = \{\omega / \omega \text{ is compatible with } B \text{ having a negative reduced cost}\}$$

Let  $x_B$  optimal solution of  $RP_B$

Let  $I = \{d + 1, \dots, n\}$  the index set of incompatible columns,  $\omega = \sum_{i \in I} v_i A_i$  with

$$\sum_{i \in I} v_i = 1, \quad \bar{c}_\omega = \sum_{i \in I} v_i \bar{c}_i.$$

$$\Omega = \{\omega / \omega \text{ is compatible with } B \text{ having a negative reduced cost}\}$$

Let  $x_B$  optimal solution of  $RP_B$

### Theorem

$x_B$  is optimal for  $LP$

$$\Omega = \emptyset$$

Let  $I = \{d + 1, \dots, n\}$  the index set of incompatible columns,  $\omega = \sum_{i \in I} v_i A_i$  with

$$\sum_{i \in I} v_i = 1, \quad \bar{c}_\omega = \sum_{i \in I} v_i \bar{c}_i.$$

$$\Omega = \{\omega / \omega \text{ is compatible with } B \text{ having a negative reduced cost}\}$$

Let  $x_B$  optimal solution of  $RP_B$

### Theorem

$x_B$  is optimal for  $LP$

$$\Omega = \emptyset \iff z_B^{CP} \geq 0.$$

## When columns are not known a priori

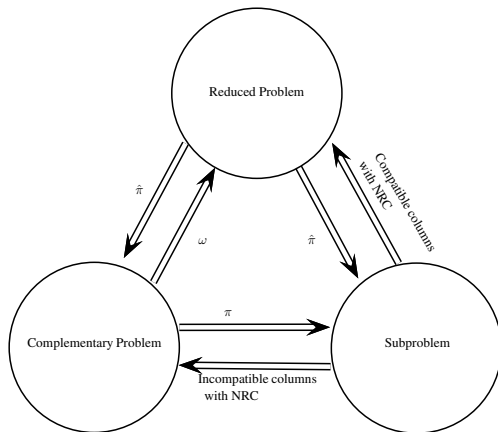

Figure 5: Column generation with three levels

- 1 Introduction
- 2 Improved Primal Simplex IPS
  - The reduced problem
  - The complementarity problem
  - IPS Non-aggregated Algorithm: IPS-N
  - Compatibility Matrix
- 3 Column generation for degenerate linear programs
  - Aggregated columns
  - IPS aggregated Algorithm: IPS-A
  - Numerical results
- 4 IPS specialization to set partitioning problems

A set partitioning model (SPP) is a special case of (LP) when  $x$  is binary,  $A$  is  $0 - 1$  matrix and  $b$  is  $e = (1, 1, \dots, 1)^T$ . We can group the tasks into clusters

Figure 6: Clusters in (SPP)

In the reduced formulation of (SPP), we have one constraint for each cluster instead of a constraint for each task.

## DCA and MPDCA algorithm

### DCA Algorithm

- In DCA Algorithm, the dual variables for the discarded rows are computed by a heuristic procedure based on solving shortest path problems.
- They apply a change of variables to transform the sub-problem to a system of difference inequalities. This system corresponds to the dual of a shortest path problem in an oriented network  $G$

### MPDCA Algorithm

- In MPDCA Algorithm: only slightly incompatible variables are considered at each iteration (K-phase).
- More and more incompatible variables are priced out for the initial partition.
- This strategy avoids a fast increase of the basis size because only slightly incompatible variables are considered at each iteration.

## Some results

- The cost of an arc in  $G$  corresponds to the partial reduced cost of its corresponding column in IPS.
- Each negative cycle in  $G$  is a convex combination having a negative reduced cost. When added this cycle to a nondegenerate aggregated problem, the objective function decreases.
- The cycle corresponding to  $\min_i \frac{\tilde{C}_i}{|F_i|}$  is the cycle that the complementary problem  $CP_Q$  outputs.
- When we run a shortest path algorithm on  $G$ , we have two cases:
  - 1 detect a negative cycle (convex combination with a negative reduced cost) that decreases the objective value of a nondegenerate aggregated problem or
  - 2 obtain a dual solution that is feasible for the incompatible columns present in  $G$ .

## Some results

- The cost of an arc in  $G$  corresponds to the partial reduced cost of its corresponding column in IPS.
- Each negative cycle in  $G$  is a convex combination having a negative reduced cost. When added this cycle to a nondegenerate aggregated problem, the objective function decreases.
- The cycle corresponding to  $\min_i \frac{\tilde{C}_i}{|F_i|}$  is the cycle that the complementary problem  $CP_Q$  outputs.
- When we run a shortest path algorithm on  $G$ , we have two cases:
  - 1 detect a negative cycle (convex combination with a negative reduced cost) that decreases the objective value of a nondegenerate aggregated problem or
  - 2 obtain a dual solution that is feasible for the incompatible columns present in  $G$ .

This results generalizes and improves MPDCA

## Compatibility Matrix in SPP case

The compatibility matrix in SPP case:

$$M = \begin{pmatrix} M_1 & & & 0 \\ & M_2 & & \\ & & \ddots & \\ 0 & & & M_{|L|} \end{pmatrix}$$

where  $M_l$  is the compatibility matrix of cluster  $l$ .

## Bus driver scheduling or VCS case

The compatibility matrix in this case:

$$(M_l)_{\substack{1 \leq i \leq n_l - 1 \\ 1 \leq j \leq n_l}} = \begin{pmatrix} 1 & -1 & 0 & \cdots & 0 \\ 1 & 0 & -1 & \ddots & \vdots \\ \vdots & \vdots & \ddots & \ddots & 0 \\ 1 & 0 & \cdots & 0 & -1 \end{pmatrix} \text{ where } n_l \text{ is the number of tasks}$$

in cluster  $l$ . Consecutive tasks on initial path will probably be consecutive in the final solution.

## Compatibility Matrix in SPP case

### Facility location , MDVSP,...

The compatibility matrix in this case:

$$(M_l)_{\substack{1 \leq i \leq n_l - 1 \\ 1 \leq j \leq n_l}} = \begin{pmatrix} 1 & -1 & 0 & \dots & 0 \\ 0 & 1 & \ddots & \ddots & \vdots \\ \vdots & \ddots & \ddots & -1 & 0 \\ 0 & \dots & 0 & 1 & -1 \end{pmatrix} . \text{ where } n_l \text{ is the number of}$$

tasks in cluster  $l$ .

### Proposition

*A column  $A_j$  is  $k$ -incompatible if and only if  $MA_j$  has  $k$  nonzero elements (1 or -1).*
