1 Dual Variable Stabilization (DVS)

2 Dynamic Constraint Aggregation (DCA)

3 Stabilized Dynamic Constraint Aggregation (SDCA)

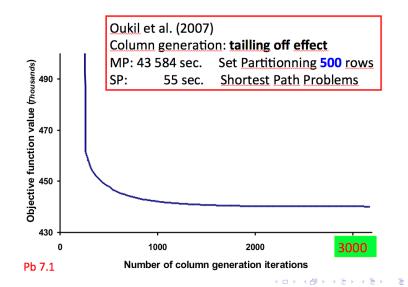

Primal-Dual pair of a linear problem

(<i>P</i>)	\min_{λ}	$\sum_{x\in\Delta}c_x\lambda_x$	(1)
	s.t.	$\sum_{egin{smallmatrix} \mathbf{a}_{X} \lambda_{X} = \mathbf{b} \qquad [m{\pi} \in \mathbb{R}^m] \end{cases}$	(2)
		$\lambda_x \geq 0, \qquad \forall x \in \Delta$	(3)
(<i>D</i>)	\max_{π}	${\pmb \pi}^{ op} {\mathbf b}$	(4)
	s.t.	$\boldsymbol{\pi}^{ op} \mathbf{a}_x \leq c_x, \qquad orall x \in \Delta$	(5)

 Δ is a finite set of combinatorial objects.

Rows (or *tasks*) in (2) are indexed by $t \in T := \{1, \ldots, m\}$.

Motivation

Motivation

∃⇒

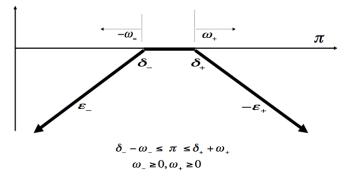

1.- Dual Variable Stabilization (DVS)

du Merle et al. (1999), Oukil et al. (2007), Ben Amor et al. (2009)

DVS penalizes a large portion of the dual solution space.

A penalty function $f_t(\pi_t)$, $\forall t \in T$:

continuous, concave, symmetric, and piecewise linear with 3 pieces.

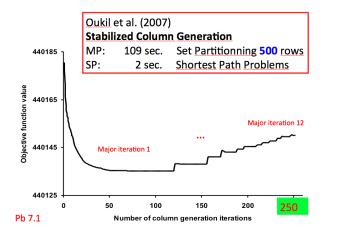

Stabilization in the primal space

$P^{\varepsilon\delta}$: A relaxation of the primal problem P_{Δ}

$(P^{arepsilon\delta})$	$\min_{\lambda,y}$	$\sum_{x\in\Delta} oldsymbol{c}_x \lambda_x - oldsymbol{\delta}^ op oldsymbol{y} + oldsymbol{\delta}_+^ op oldsymbol{y}_+$		(6)
	s.t.	$\sum_{\mathbf{x}\in \mathbf{\Delta}} \mathbf{a}_{\mathbf{x}}\lambda_{\mathbf{x}} - \mathbf{y}_{-} + \mathbf{y}_{+} = \mathbf{b}$	$[m{\pi} \in \mathbb{R}^m]$	(7)
		$0 \leq \mathbf{y}_{-} \leq \mathbf{arepsilon}_{-}$	$[oldsymbol{\omega}_{-}\in\mathbb{R}^{m}]$	(8)
		$0 \leq \mathbf{y}_+ \leq arepsilon_+$	$[oldsymbol{\omega}_+\in\mathbb{R}^m]$	(9)
		$\lambda_x \ge 0, \qquad \forall x \in \Delta$	((10)

To solve P, a sequence of linear approximations (<u>relaxations</u>), i.e., stabilized problems P^s ($s \ge 1$) are solved with ε^s and δ^s yielding objective values $z^1 < z^2 < ... < z^s < ... \le z^*$.

To solve P, a sequence of linear approximations (<u>relaxations</u>), i.e., stabilized problems P^s ($s \ge 1$) are solved with ε^s and δ^s yielding objective values $z^1 < z^2 < ... < z^s < ... \le z^*$.

DVS algorithm

- 1: Set s := 1 and choose stabilization parameters ε^s and δ^s .
- 2: Solve stabilized problem P^s : $(\lambda^s, \mathbf{y}^s)$.
- 3: if $y^s = 0$ then
- 4: Stop. λ^s is optimal to *P*.
- 5: **else**
- 6: s:=s+1, update ε^s and δ^s , and return to Step 2.

2.- Dynamic Constraint Aggregation (DCA) for set partitioning problems

Let $Q := \{T_\ell\}_{\ell \in L}$ b	e a partition of the rows of T into cluste	ers.
$(P_Q) \min_{\lambda}$	$\sum_{x\in \Delta_Q} c_x \lambda_x$	(11)
s.t.	$\sum_{x\in \Delta_Q} \mathbf{a}_{Q\mathbf{x}} \lambda_{\mathbf{x}} = 1 \qquad [\pi_Q \in \mathbb{R}^{ L }]$	(12)
	$\lambda_x \ge 0, \qquad \forall x \in \Delta_Q$	(13)

column $\mathbf{a}_{Q_X} \in \{0,1\}^{|L|}$ is a clustered version of $\mathbf{a}_X \in \{0,1\}^m$: component $\mathbf{a}_{Q_X\ell} = 1$ if object x selects cluster $\ell \in L$, 0 otherwise.

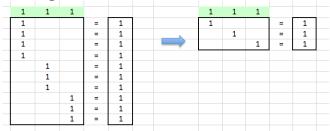

Each subset of identical rows defines a cluster in Q

From an integer solution

	1	1	1				1	1	1			
Г	1			=	1		1			=	1	
	1			=	1			1		=	1	
	1			=	1				1	=	1	
	1			=	1							
		1		=	1							
		1		=	1							
		1		=	1							
			1	=	1							
			1	=	1							
			1	=	1							

Each subset of identical rows defines a cluster in Q

From an integer solution

From a fractional solution

To solve P, a sequence of row-aggregated problems P_{Q_h} $(h \ge 1)$ are solved with various row-partitions Q_h , yielding objective values $z_1 \ge z_2 \ge ... \ge z_h \ge ... \ge z^*$. To solve P, a sequence of row-aggregated problems P_{Q_h} $(h \ge 1)$ are solved with various row-partitions Q_h , yielding objective values $z_1 \ge z_2 \ge ... \ge z_h \ge ... \ge z^*$.

A column generation process

P is solved using various clusters until an equivalence with the original problem.

To solve P, a sequence of row-aggregated problems P_{Q_h} $(h \ge 1)$ are solved with various row-partitions Q_h , yielding objective values $z_1 \ge z_2 \ge ... \ge z_h \ge ... \ge z^*$.

A column generation process

P is solved using various clusters until an equivalence with the original problem.

λ_{Q_h} is optimal to P if

there is no negative reduced cost variables with respect to some disaggregated dual vector $\pi \in \mathbb{R}^m$.

DCA algorithm for set partitioning problems

- 1: Select a row-partition Q.
- 2: Solve row-aggregated problem P_Q : $(\lambda_Q; \pi_Q)$.
- 3: Disaggregate the dual vector π_Q to compute $\pi \in \mathbb{R}^m$.
- 4: Check if there exist negative reduced cost variables.
- 5: if no such variables exist then
- 6: Stop. λ_Q is optimal for *P*.
- 7: **else**
- 8: Update *Q* using a few negative reduced cost variables, and return to Step 2.

(Each subset of identical rows defines a cluster.)

Dual variable disaggregation for set partitioning problems

A sufficient condition:

$$\sum_{t\in \mathcal{T}_{\ell}} \pi_t = \pi_{Q\ell}, \qquad \forall \ell \in L.$$
 (14)

Dual variable disaggregation for set partitioning problems

A sufficient condition:
$$\sum_{t \in T_{\ell}} \pi_t = \pi_{Q\ell}, \quad \forall \ell \in L.$$
 (14)

Incompatible variables in $\Delta_{\bar{Q}_1}$ and $\Delta_{\bar{Q}_2}$ (Elhallaoui et al. 2005)

Since the sum of the dual variables in cluster ℓ is known by (14), the non-negativity constraints on the reduced costs of variables λ_x , $x \in \Delta_{\bar{Q}_1} \cup \Delta_{\bar{Q}_2}$, can be transformed into difference inequalities, i.e., the disaggregation is the solution of a shortest path problem.

An incompatible column in $\Delta_{\bar{Q}_1}$ partially covers a single cluster whereas a column in $\Delta_{\bar{Q}_2}$ is incompatible with two.

SDCA: Stabilized & row-aggregated problem

<ロ> <昂> < 言> < 言> < 言> と言う こののの 17/27

SDCA: Stabilized & row-aggregated problem

Proposition 2

Row-aggregated parameters: $P^s \rightarrow P^s_O$ For all $\ell \in I$ $\varepsilon_{Q-\ell}^{s} := \min_{t \in \mathcal{T}_{\ell}} \{ \varepsilon_{-,t}^{s} \}, \qquad \varepsilon_{Q+\ell}^{s} := \min_{t \in \mathcal{T}_{\ell}} \{ \varepsilon_{+,t}^{s} \};$ $\delta_{Q-\ell}^{\mathbf{s}} := \sum_{t \in T_{\ell}} \delta_{-,t}^{\mathbf{s}}, \qquad \delta_{Q+\ell}^{\mathbf{s}} := \sum_{t \in T_{\ell}} \delta_{+,t}^{\mathbf{s}}$ Stabilized primal solution: $P_{\Omega}^{s} \rightarrow P^{s}$ $\lambda_x^s := \lambda_{Ox}^s, \forall x \in \Delta_O \qquad \lambda_x^s := 0, \ \forall x \in \Delta \setminus \Delta_O$ $y_{-t}^s := y_{Q-\ell}^s$ and $y_{+t}^s := y_{Q+\ell}^s$, $\forall t \in T_\ell, \ell \in L$,

SDCA: Dual variable disaggregation

Define
$$\beta_{\ell,i}^s := \sum_{j=1}^l \pi_{\ell,j}^s, \quad \forall \ell \in L, i \in \{1, \dots, |T_\ell|\}.$$

The system of difference inequalities takes into account, for each constraint $t \in T$, the trust region carried out by the δ -parameters.

$$\begin{split} \beta^{s}_{\ell,i} - \beta^{s}_{\ell,i-1} &= \pi^{s}_{Q,\ell}, \qquad \forall \ell \in L \\ \beta^{s}_{\ell,i} - \beta^{s}_{\ell,i-1} &\geq \delta^{s}_{-,t}, \qquad \forall t = (\ell,i) \in T \text{ such that } y^{s}_{-,t} = 0 \\ \beta^{s}_{\ell,i} - \beta^{s}_{\ell,i-1} &= \delta^{s}_{-,t}, \qquad \forall t = (\ell,i) \in T \text{ such that } 0 < y^{s}_{-,t} < \varepsilon^{s}_{-,t} \\ \beta^{s}_{\ell,i} - \beta^{s}_{\ell,i-1} &\leq \delta^{s}_{-,t}, \qquad \forall t = (\ell,i) \in T \text{ such that } y^{s}_{-,t} = \varepsilon^{s}_{-,t} \\ \beta^{s}_{\ell,i} - \beta^{s}_{\ell,i-1} &\leq \delta^{s}_{+,t}, \qquad \forall t = (\ell,i) \in T \text{ such that } y^{s}_{+,t} = 0 \\ \beta^{s}_{\ell,i} - \beta^{s}_{\ell,i-1} &= \delta^{s}_{+,t}, \qquad \forall t = (\ell,i) \in T \text{ such that } 0 < y^{s}_{+,t} < \varepsilon^{s}_{+,t} \\ \beta^{s}_{\ell,i} - \beta^{s}_{\ell,i-1} &\geq \delta^{s}_{+,t}, \qquad \forall t = (\ell,i) \in T \text{ such that } y^{s}_{+,t} = \varepsilon^{s}_{+,t}. \end{split}$$

Still solvable as a shortest path problem.

Results-3: DVS vs. SDCA

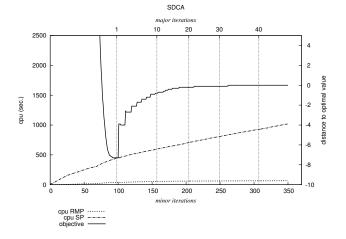

Figure: SDCA for a 2500-task, 5-day scenario

Computational Experiments

Stabilized Dynamic Constraint Aggregation (SDCA) within Column Generation

Set Partitioning model for the MDVSP.

Random instances using the procedure of Carpaneto et al. (1989), modified by Oukil et al. (2007) to adjust the level of degeneracy.

3 depots and between 500 and 3000 tasks spread over 2 or 5 days.

5-day instances are highly degenerate.

For each row-size, reported results are average over 6 instances.
