The problem	The algorithm	Applications to clustering	Computational experience	Conclusions
Problem definition				

- Given a set V,
- find a partition P(V) of the set V
- so as to minimize a cost function f(P(V))

With the three additional properties:

- $U \subseteq V \Longrightarrow f(P^*(U)) \leq f(P^*(V))$ (monotonicity)
- $\exists U \subseteq V, |U| \ll |V|$ such that
 - $f(P^*(U)) = f(P^*(V))$ (degeneracy)
 - Possible to build P*(V) from enlarging P*(U) (constructibility)

Conclusions

The minimax diameter clustering problem

State-of-the-art algorithms

- Complete linkage: most popular heuristic method
- Constraint Programming: most efficient exact method
 - Can solve problems containing up to 5k observations

Both methods:

- need to compute and store the dissimilarity matrix (cpu = mem = O(n²))
- therefore, they cannot be applied to large problems

The minimax diameter clustering problem				
Observa	ations			

Complete problem contains 14 observations

- Largest Exact SPP (U, k) contains only 5 nodes
- The dissimilarity matrix must only be stored for these smaller problems
 - No storage problems
 - In practice, our method is faster than computing the dissimilarity matrix (still O(n²) in practice though)
- Ordering of the nodes for the heuristic is critical (most likely to result in an infeasible insertion are inspected first)
- The bottleneck of our algorithm is HeuristicSPP $(P^U, V \setminus U)$! $(O(n^3)$ in the worst case but $O(n^2)$ in practice)

Table: Detailed results on the chunking method

The problem ○	The algorithm	Applications to clustering	Computational experience	Conclusions
Conclus	ions			

- Our method seems to be very sensitive to noise. Noisy problems (Birch1, 2, 3, pendigits) could not be solved although smaller in size
- We are currently testing our framework to solve other classification problems presenting high degrees of degeneracy
- The method seems easily adaptable to become a heuristic capable of handling larger problems (as in *online streaming of data*)
